Mark Kurlansky’s book, *The Unnatural History of the Sea,* is a compelling read. The book is divided into chapters titled “The First Fish” and “The First Fishermen.” Kurlansky explores the history of human interaction with the sea, from the prehistoric era to modern times. His narrative style is engaging, and he manages to inject a sense of wonder and excitement into the topic.

The book covers a wide range of subjects, from the origins of fishing to the current state of the oceans. Kurlansky highlights the impact of human activities on the marine environment and the need for responsible management of marine resources. He also discusses the role of scientists and politicians in addressing these issues.

Kurlansky uses a variety of sources to support his arguments, including scientific papers, government reports, and personal anecdotes. His writing is concise and well-organized, making it easy to follow along with the narrative.

Overall, *The Unnatural History of the Sea* is an informative and entertaining read for anyone interested in the natural history of the sea and the impact of human activities on the marine environment.
for most fish species but both species of mudminnows have been observed spawning outdoors around the time the ice melts, the very edge of the ice on the swamp was another poor water conditions. Their swim bladder is physostomous which means there is a duct connecting the bladder to the gills. These fish possess vascular sections of the swim bladder. This allows them to breathe air. As it turns out their unique swim bladder appears to be the key to their survival and they can survive hypoxic conditions that kill many other fish (Klingler et al. 1982; Chilton et al. 1984). These Central Mudminnows can survive hypoxic conditions that kill many other fish. Apparently spring wasn't only just in the air but in the mudminnow water as well. Mudminnows appear to prefer spawning in the earliest spring or even before spring. More evidence of this is found in our own NANFA forum. Mudminnows have very active wintering habits. In winter, Central Mudminnows can swim against the stream and in some cases can be found in upstream of the spawning areas. Study Design:
We conducted monthly seining collections of Ironcolor Shiner in the upper San Marcos River between January and December of 2007. Sampling sites varied by month, but were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were throughout the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River. No more than 12 individuals were opportunistically sampled by month and seines were always within the 2.2 km urbanized reach of the San Marcos River.
